A comparative genetic and epidemiological study of two isolated and unrelated villages from Northern Italy (1978-2007). We conducted an epidemiological and genetic study of two isolated and unrelated Italian villages, Pirago and Natisone, in the Northern Apennines, to evaluate the role of geographic isolation and of the genetic isolation in determining the observed differences in susceptibility to leprosy between the two villages and in the risk of transmission. We observed higher prevalence rates in the Pirago village compared to that of Natisone, in both endemic-new and endemic-chronic leprosy, but this difference did not reach statistical significance for endemic-chronic disease. The data for transmission risk indicate that genetically isolated villages like Pirago and Natisone, which are closer to one another than to larger towns, can increase the risk of genetic isolation and transmission because of the overlap of genetic pools and gene flow. This invention is concerned with co-authored items and the like, and more particularly concerns the display of co-authored items such as charts, reports, graphs, etc., which may have a varied number of authors. There are many applications in which co-authored items are provided as a convenience to the reader. Such co-authored items are typically provided from the author's office so that the reader need not make a special trip. The problem with co-authored items from the publisher's office is that the publisher cannot be assured of getting credit for the item, or in the event of some problem with the item, cannot be certain that it will be replaced or if replaced will be replaced at a lower cost. In the electronic age, the problem of postage and handling costs is even more of a problem. Applicants have discovered a method and apparatus for displaying co-authored items which allows the co-auth
